Let **P** be the plane $3x + 2y + 3z = 16$ and let
$S : \alpha\hat{i} + \beta\hat{j} + \gamma\hat{k}$, where $\alpha + \beta + \gamma = 7$ and the distance of (α, β, γ) from the plane is $\frac{2}{\sqrt{22}}$. Let **u**, **v**, **w** be three distinct vectors in S such that $|\mathbf{u} - \mathbf{v}| = |\mathbf{v} - \mathbf{w}| = |\mathbf{w} - \mathbf{u}|$. Let V be the volume of the parallelepiped determined by vectors **u**, **v**, **w**. Then the value of $\frac{80}{3}V$ is _____.

Theoretical Solution

Let the matrix of vectors be $\mathbf{A} = \begin{pmatrix} \mathbf{u} & \mathbf{v} & \mathbf{w} \end{pmatrix}$. The volume $V = \left\| \mathbf{A} \right\|$. Let $\mathbf{x} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$. The condition that the points lie on the plane $\alpha + \beta + \gamma = k_1$ where $k_1 = 7$ is:

$$\mathbf{A}^\top \mathbf{x} = k_1 \mathbf{x} \tag{1}$$

So, k_1 is an eigenvalue of $\mathbf{A}^\top$ and hence an eigenvalue of $\mathbf{A}$.

Theoretical Solution

The vectors representing the sides of the equilateral triangle are

$$\mathbf{u} - \mathbf{v} = \mathbf{A}\mathbf{c_1} \tag{2}$$

$$\mathbf{v} - \mathbf{w} = \mathbf{A}\mathbf{c_2} \tag{3}$$

$$\mathbf{w} - \mathbf{u} = \mathbf{A}\mathbf{c_3} \tag{4}$$

where $\mathbf{c_1} = \begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}, \mathbf{c_2} = \begin{pmatrix} 0 \\ 1 \\ -1 \end{pmatrix}, \mathbf{c_3} = \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}.$

The condition $\|\mathbf{u} - \mathbf{v}\| = \|\mathbf{v} - \mathbf{w}\| = \|\mathbf{w} - \mathbf{u}\| = L$ implies:

$$\left(\mathbf{A}\mathbf{c_1}\right)^\top \left(\mathbf{A}\mathbf{c_1}\right) = \left(\mathbf{A}\mathbf{c_2}\right)^\top \left(\mathbf{A}\mathbf{c_2}\right) = \left(\mathbf{A}\mathbf{c_3}\right)^\top \left(\mathbf{A}\mathbf{c_3}\right) = L^2 \tag{5}$$

$$V^2 = \left| \mathbf{G} \right| \tag{6}$$

where the Gram matrix is $\mathbf{G} = \mathbf{A}^\top \mathbf{A}$. From (1), we find an eigenvector of $\mathbf{G}$:

$$\mathbf{G}\mathbf{x} = \mathbf{A}^\top \mathbf{A}\mathbf{x} \tag{7}$$

$$= \mathbf{A}^\top \left(k_1 \mathbf{x} \right) \tag{8}$$

$$= k_1 \left(\mathbf{A}^\top \mathbf{x} \right) \tag{9}$$

$$= k_1 \left(k_1 \mathbf{x} \right) \tag{10}$$

$$= k_1^2 \mathbf{x} \tag{11}$$

So, $\lambda_1 = k_1^2$ is an eigenvalue of $\mathbf{G}$ with eigenvector $\mathbf{x}$.

(5) can be written in terms of $\mathbf{G}$ as

$$\mathbf{c_i}^\top \mathbf{G} \mathbf{c_i} = L^2 \text{ for } i = 1, 2, 3 \tag{12}$$

The vectors $\mathbf{c_i}$ are orthogonal to $\mathbf{x}$ because $\mathbf{x}^\top \mathbf{c_i} = 0$ and lie in a 2D subspace W.

Since $\mathbf{G}$ is symmetric, its other two eigenvectors, $\mathbf{e_2}, \mathbf{e_3}$, span W.

Let their eigenvalues be λ_2, λ_3.

$\because \mathbf{c_1}^\top \mathbf{G} \mathbf{c_1} = L^2$ and $\mathbf{c_2}^\top \mathbf{G} \mathbf{c_2} = L^2; \|\mathbf{c_1}\|^2 = 2$ and $\|\mathbf{c_2}\|^2 = 2$, the quadratic form defined by $\mathbf{G}$ is constant on a circle (The ellipse becomes a circle due to equal distance of the points from centre) in the subspace W. This requires the eigenvalues corresponding to this subspace to be equal: $\lambda_2 = \lambda_3 = \lambda$.

Theoretical Solution

Therefore, for any vector $\mathbf{w} \in W$, $\mathbf{w}^\top \mathbf{G} \mathbf{w} = \lambda \|\mathbf{w}\|^2$. Using $\mathbf{c_1}$:

$$\mathbf{c_1}^\top \mathbf{G} \mathbf{c_1} = \lambda \|\mathbf{c_1}\|^2 \tag{13}$$

$$L^2 = \lambda\,(2) \tag{14}$$

$$\lambda = \frac{L^2}{2} \tag{15}$$

The eigenvalues of $\mathbf{G}$ are $k_1^2, \frac{L^2}{2}, \frac{L^2}{2}$. The determinant of $\mathbf{G}$ is the product of its eigenvalues:

$$\left|\mathbf{G}\right| = k_1^2 \left(\frac{L^2}{2}\right) \left(\frac{L^2}{2}\right) = \frac{k_1^2 L^4}{4} \tag{16}$$

The volume is

$$V = \sqrt{\left|\mathbf{G}\right|} = \frac{k_1 L^2}{2} \tag{17}$$

Theoretical Solution

$$\mathbf{P} : 3x + 2y + 3z = 16 \implies \mathbf{n} = \begin{pmatrix} 3 \\ 2 \\ 3 \end{pmatrix}, k_2 = 16 \tag{18}$$

$$x + y + z = 7 \implies \mathbf{n_1} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}, k_1 = 7 \tag{19}$$

$$\tag{20}$$

The distance condition gives two planes $\mathbf{P_1} : 3x + 2y + 3z = 18$ and
$\mathbf{P_2} : 3x + 2y + 3z = 14$.
Let altitude of the triangle be h_T

$$h_T = \frac{d_{P_1 P_2}}{\sin \theta}, \text{ where } \theta \text{ is the angle between the plane normals.} \tag{21}$$

$$d_{P_1 P_2} = \frac{|18 - 14|}{\|\mathbf{n}\|} = \frac{4}{\sqrt{22}} \tag{22}$$

Theoretical Solution

$$\sin \theta = \sqrt{1 - \left(\frac{\mathbf{n}^\top \mathbf{n_1}}{\|\mathbf{n}\| \, \|\mathbf{n_1}\|} \right)^2} = \sqrt{1 - \left(\frac{8}{\sqrt{22} \, \sqrt{3}} \right)^2} = \frac{1}{\sqrt{33}} \qquad (24)$$

$$h_T = \frac{4/\sqrt{22}}{1/\sqrt{33}} = 4\sqrt{\frac{3}{2}} \qquad (25)$$

$$L^2 = \left(\frac{2}{\sqrt{3}} h_T \right)^2 = \frac{4}{3} \left(16 \times \frac{3}{2} \right) = 32 \qquad (26)$$

$$V = \frac{|7| \, (32)}{2} = 112 \qquad (27)$$

$$\therefore \frac{80}{3} V = \frac{80}{3} (112) = \frac{8960}{3} \qquad (28)$$
